- Examples: Bridge, multidim Newton's method, QM, vibrational eigenmodes
- 2 Linear equations
- **3** Gauss elimination, Pivoting
- 4 Numerical errors, condition number
- 5 LU decomposition, iterative improvement
- 6 Householder reduction
- iterative solution: Gauss-Seidel, Successive overrelaxation (SOR), Conjugate gradient (CG) and others

Householder reduction

We still want to solve $A\mathbf{x} = b$. We have used Gauss elimination, LU decomposition, and that pivoting is typically needed.

Householder reduction

using orthogonal transformations, we bring the matrix to a triangular form:

$$OA = R$$
 (1)

where O is orthogonal: $O^T O = OO^T = \mathbf{1}$,

if we have two orthogonals: O_1, O_2

$$O_1 O_2 (O_1 O_2)^T = O_1 O_2 O_2^T O_1^T = \mathbf{1}$$
 (2)

 \implies their product is also orthogonal

R is upper triangular : $R_{ij} = 0$ for i > j

Householder reduction

Can also think of it as factorization: $A = O^T R$

$$A\mathbf{x} = \mathbf{b} \implies O^T R\mathbf{x} = \mathbf{b} \implies O^T \mathbf{y} = \mathbf{b}, R\mathbf{x} = \mathbf{y}$$
 (3)

 $O^T \mathbf{y} = \mathbf{b}$ is solved simply using $\mathbf{y} = O\mathbf{b}$ $R\mathbf{x} = \mathbf{y}$ is solved using backsubstitution

Replaces Gauss elimination (LU decomposition)

numerically stable since it uses orthogonal transformations

O is a product of reflections

Reflections in *n* dimensions

Take a unit vector \mathbf{w} , $\mathbf{w}^T \mathbf{w} = 1$ This defines an n-1 dimensional hyperplane of vectors orthogonal to \mathbf{w}

we want the reflection $\mathbf{x} \to P \mathbf{x}$

$$\begin{aligned} \mathbf{x}_{\parallel} &= (\mathbf{w}^{T}\mathbf{x})\mathbf{w}: \text{ projection to } \mathbf{w} \\ \mathbf{x} &= \mathbf{x}_{\parallel} + \mathbf{x}_{\perp} \rightarrow P\mathbf{x} = -\mathbf{x}_{\parallel} + \mathbf{x}_{\perp} = \mathbf{x} - 2\mathbf{x}_{\parallel} \\ P\mathbf{x} &= \mathbf{x} - 2\mathbf{w}(\mathbf{w}^{T}\mathbf{x}) = (\mathbf{1} - 2\mathbf{w}\mathbf{w}^{T})\mathbf{x} \\ \text{outer product: } \mathbf{w}\mathbf{w}^{T} = M, \quad M_{ij} = \mathbf{w}_{i}\mathbf{w}_{j} \end{aligned}$$

Reflections in *n* dimensions

$$P = (\mathbf{1} - 2\mathbf{w}\mathbf{w}^T)$$

 P is symmetric: $P^T = P$

$$P^{2} = (1 - 2\mathbf{w}\mathbf{w}^{T})(1 - 2\mathbf{w}\mathbf{w}^{T}) = 1 - 4\mathbf{w}\mathbf{w}^{T} + 4\mathbf{w}\underbrace{\mathbf{w}^{T}\mathbf{w}}_{1}\mathbf{w}^{T} = 1$$
(4)

as w is a unit vector: $\mathbf{w}_j \mathbf{w}_j = 1 \implies \mathbf{w}_i \mathbf{w}_j \mathbf{w}_j \mathbf{w}_k = \mathbf{w}_i \mathbf{w}_k$

 \implies P is orthogonal: $P^T P = PP^T = P^2 = 1$

Reflections in *n* dimensions

▲ロト ▲帰 ト ▲ ヨ ト ▲ ヨ ト ・ ヨ ・ の Q ()

Can we bring any two vectors in to each other with a reflection?

given $\mathbf{x} \neq \mathbf{y}$ two vectors with the same length $\mathbf{x}^T \mathbf{x} = \|\mathbf{x}\|^2 = \|\mathbf{y}\|^2 =$ $\mathbf{y}^T \mathbf{y} \implies$ There exists a reflection such that $P\mathbf{x} = \mathbf{y}, P\mathbf{y} = \mathbf{x}$

Proof:
$$\mathbf{w} = \frac{\mathbf{x} - \mathbf{y}}{\|\mathbf{x} - \mathbf{y}\|}$$

 $(\mathbf{w}\mathbf{w}^T)\mathbf{x} = (\mathbf{x} - \mathbf{y})\frac{(\mathbf{x}^T - \mathbf{y}^T)\mathbf{x}}{\|\mathbf{x} - \mathbf{y}\|^2} = (\mathbf{x} - \mathbf{y})\frac{(\mathbf{x}^T\mathbf{x} + \mathbf{y}^T\mathbf{y} - \mathbf{y}^T\mathbf{x} - \mathbf{x}^T\mathbf{y})}{2\|\mathbf{x} - \mathbf{y}\|^2} =$
 $= (\mathbf{x} - \mathbf{y})\frac{(\mathbf{x} - \mathbf{y})^T(\mathbf{x} - \mathbf{y})}{2\|\mathbf{x} - \mathbf{y}\|^2} = \frac{\mathbf{x} - \mathbf{y}}{2}$

$$\implies P\mathbf{x} = (1 - 2\mathbf{w}\mathbf{w}^{\mathsf{T}})\mathbf{x} = \mathbf{x} - 2\frac{\mathbf{x} - \mathbf{y}}{2} = \mathbf{y}$$
(5)

Householder reduction step 1

construct reflection such that

$$\mathbf{a}^{1} = \begin{pmatrix} \mathbf{a}_{11} \\ \mathbf{a}_{21} \\ \vdots \\ \mathbf{a}_{n1} \end{pmatrix} \xrightarrow{P_{1}\mathbf{a}^{1}} \begin{pmatrix} -\sigma_{1} \\ \mathbf{0} \\ \vdots \\ \mathbf{0} \end{pmatrix} \qquad P_{1}\underbrace{\mathbf{a}^{1}}_{=x} = \underbrace{-\sigma_{1}\mathbf{e}_{1}}_{=y} \text{ with } \sigma_{1} = \pm \left\| \mathbf{a}^{1} \right\| \qquad (6)$$

$$\mathbf{u}^{T} = (\mathbf{x} - \mathbf{y})^{T} = (a_{11} + \sigma_1, a_{21}, \dots, a_{n1}), \qquad P_1 = 1 - \mathbf{u}\mathbf{u}^{T}/H$$
(7)

$$H = \frac{1}{2}u^{T}u = \frac{1}{2}(a^{1} + \sigma_{1}\mathbf{e}_{1})(a^{1} + \sigma_{1}\mathbf{e}_{1}) = \frac{1}{2}(\|a^{1}\|^{2} + 2\sigma_{1}a_{11} + \sigma_{1}^{2}) = \sigma_{1}(\sigma_{1} + a_{11}) \quad (8)$$

avoiding precision loss if $\operatorname{sign}\sigma_1 = \operatorname{sign}a_{11} \implies \sigma_1 = \operatorname{sign}(a_{11}) \|a^1\|$ No pivoting required, the diagonal always becomes $\|a^1\|$. If that is zero, the matrix is singular

Householder reduction 2nd step

After first step
$$a_{ij} \to a'_{ij} = (P_1 A)_{ij}$$

2nd step: $\mathbf{u}^T = (0, a'_{22} + \sigma_2, a'_{32}, \dots, a'_{n2}), \qquad \sigma_2 = \operatorname{sign}(a'_{22})\sqrt{\sum_{i=2}^n (a'_{i2})^2}$

$$P_{2} = 1 - \mathbf{u}\mathbf{u}^{T}/H = \begin{pmatrix} 1 & 0 & \cdots & 0 \\ 0 & & \\ \vdots & & \mathbf{X} \end{pmatrix}, \qquad H = \sigma_{2}(\sigma_{2} + a_{22}')$$
(9)

$$P_{2}P_{1}A = \begin{pmatrix} -\sigma_{1} & a'_{12} & \cdots & a'_{1n} \\ 0 & -\sigma_{2} & & \\ \vdots & 0 & [A''] \\ \vdots & \vdots & \\ 0 & 0 & & \end{pmatrix}$$
(10)

First row and first column of P_1A is unchanged

Householder reduction

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

Do it n-1 times: $P_{n-1} \dots P_1 A = R$ with R upper triangular $Q = (P_{n-1}P_{n-2} \dots P_2P_1)^T = P_1P_2 \dots P_{n-2}P_{n-1}$ $A = QR \implies$ "QR decomposition"

Complex QR

$$\mathbf{x} \in \mathbb{C}^{n}, x_{1} = re^{i\Theta} \text{ with } r, \Theta \in \mathbb{R}$$

 $\mathbf{u} = \mathbf{x} \pm e^{i\Theta} ||\mathbf{x}|| \mathbf{e}_{1} \text{ and } P = 1 - \frac{\mathbf{u}\mathbf{u}^{\dagger}}{H}, \quad H = \mathbf{u}^{\dagger}\mathbf{u}/2$
 $P\mathbf{x} = \mp e^{i\theta} ||\mathbf{x}|| \mathbf{e}_{1}$
orthogonality \rightarrow unitarity

$$P^{\dagger}P = \left(1 - \frac{\mathbf{u}\mathbf{u}^{\dagger}}{H}\right)\left(1 - \frac{\mathbf{u}\mathbf{u}^{\dagger}}{H}\right) = 1 - 2\frac{\mathbf{u}\mathbf{u}^{\dagger}}{H} + \frac{\mathbf{u}\mathbf{u}^{\dagger}\mathbf{u}\mathbf{u}^{\dagger}}{\left(\frac{1}{2}\mathbf{u}^{\dagger}\mathbf{u}\right)^{2}} \qquad (11)$$
$$= 1 - 2\frac{\mathbf{u}\mathbf{u}^{\dagger}}{H} + 2\frac{\mathbf{u}\mathbf{u}^{\dagger}}{H} = 1 \qquad (12)$$

sign choosen to maximize H

```
cost of LU decomposition: O(n^3)
matrix multiplication: O(n^3), need n-1 reflections: O(n^4)?
```

```
Actually multiplication with reflector is cheaper.

\mathbf{ww}^{T} = w_{i}w_{j}: calculating w_{i}w_{j}A_{jk}

First calculate v_{k} = w_{j}A_{jk}, takes O(n^{2}) operations Than a'_{ij} = a_{ij} - Cw_{i}v_{j} takes O(n^{2}) operations \implies multiplication with reflector takes O(n^{2})

\implies QR reduction needs O(n^{3})
```

 $LU \sim n^3/3$, QR reduction $\sim 2n^3/3$ but QR needs no pivoting and is numerically stable.

Iterative solution

Often one can have an iterative procedure that delivers a solution to some problem. We are interested here in the solution to $A\mathbf{x} = \mathbf{b}$ An example (not particularly efficient) let M be a matrix. The geometric series is defined as:

$$S_n = \sum_{i=0}^n M^i = 1 + M + M^2 + \ldots + M^n$$
(13)

now we can write $S_{n+1} = S_n + M^{n+1} = 1 + S_n M$ $\implies S_n(1-M) = 1 - M^{n+1}$

$$S_n = (1 - M^{n+1})(1 - M)^{-1}$$
(14)

if $M^n \xrightarrow[n \to \infty]{} 0$, than $S_\infty = (1 - M)^{-1}$ This happens if M is "small" (e.g. all eigenvalues are < 1)

Suppose *M* is diagonalizable: $M = U \operatorname{diag}(\lambda_1, \ldots, \lambda_n) U^{-1}$, with *U* orthogonal (unitary)

$$M^{k} = U \operatorname{diag}(\lambda_{1}, \dots, \lambda_{n}) \underbrace{U^{-1}U}_{=1} \operatorname{diag}(\lambda_{1}, \dots, \lambda_{n}) U^{-1} \dots =$$

$$= U(\operatorname{diag}(\lambda_{1}, \dots, \lambda_{n}))^{k} U^{-1} = U \operatorname{diag}(\lambda_{1}^{k}, \dots, \lambda_{n}^{k}) U^{-1}$$

$$\Rightarrow M^{k} \to 0 \text{ if } \lambda_{i} < 1$$
(15)

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

This leads to the following procedure: Given a matrix A, and righthandside b,

- **1** calculate the matrix M = 1 A
- **2** $v_0 = b$
- $\mathbf{3} \mathbf{v}_{i+1} = \mathbf{b} + M \mathbf{v}_i$
- 4 exit if converged
- 5 goto 3

we have calculated the geometric series using $S_{n+1} = 1 + MS_n$, applied to the vector b

by convergence we have

$$\mathbf{v} = (1 + M + \dots M^n + \dots)\mathbf{b} = (1 - M)^{-1}\mathbf{b} = A^{-1}\mathbf{b}$$
 (16)

converges only if A is "close" to the unit matrix

Jacobi method

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

We want to solve $a_{ij}x_j = b_i$ solve for x_i formally:

$$x_i = -\frac{1}{a_{ii}} \left[\sum_{j \neq i} a_{ij} x_j - b_i \right]$$
(17)

Make this into an iteration:

$$x_{i}^{(i+1)} = -\frac{1}{a_{ii}} \left[\sum_{j \neq i} a_{ij} x_{j}^{(i)} - b_{i} \right]$$
(18)

if we get $x^{(i+1)} = x^{(i)}$ we have found the solution. \implies iterate until convergence

Iterative solution of $A\mathbf{x} = \mathbf{b}$

We rewrite $A\mathbf{x} = \mathbf{b}$ in the form: $\mathbf{x} = G(\omega)\mathbf{x} + \mathbf{g}(\omega)$, where ω is a relaxation parameter We can thus define an iteration: $\mathbf{x}_{i+1} = G(\omega)\mathbf{x}_i + \mathbf{g}(\omega)$ In case of convergence

$$\mathbf{x} = \lim_{i \to \infty} \mathbf{x}_i \tag{19}$$

Procedure is not unique, depends on the choice of $G(\omega)$ and $\mathbf{g}(\omega)$ e.g. $A = N(\omega) - P(\omega)$ with $N(\omega)$ non-singular

$$(N(\omega) - P(\omega))\mathbf{x} = \mathbf{b} \implies N(\omega)\mathbf{x}_{i+1} = P(\omega)\mathbf{x}_i + \mathbf{g}(\omega)$$
 (20)

We choose $N(\omega)$ such that one can easily solve $N(\omega)\mathbf{x} = \mathbf{y}$.

$$\mathbf{x} = N^{-1}(\omega)P(\omega)\mathbf{x} + N^{-1}(\omega)\mathbf{b}$$

$$\implies G(\omega) = N^{-1}(\omega)P(\omega), \qquad \mathbf{g}(\omega) = N^{-1}(\omega)\mathbf{b}$$
(21)

Iterative solution of Ax = b

(日) (日) (日) (日) (日) (日) (日) (日)

Can be shown to converge if the spectral radius ρ of $G(\omega)$ is smaller than 1 (i.e. eigenvalues have absolute value smaller than 1)

$$\rho(G) = \max|\lambda_k(G)| \tag{22}$$

(In case $G(\omega)$ is not diagonalizable, diagonals < 1 in the Jordan normal form)

Convergence rate is given by $\lambda_{max}(G(\omega))$ The inverse of $N(\omega)$ must be easily calculable.

 $N(\omega)$ is completely arbitrary ($P(\omega) = N(\omega) - A$), but it makes sense if it is choosen to be related to A

Proof of convergence

$$\mathbf{e}_{k} = \mathbf{x}_{k} - \mathbf{x} = N^{-1} P \mathbf{x}_{k-1} + N^{-1} \mathbf{b} - (N^{-1} P \mathbf{x} + N^{-1} \mathbf{b}) = (23)$$

= $N^{-1} P (\mathbf{x}_{k-1} - \mathbf{x}) = N^{-1} P \mathbf{e}_{k-1}$

So the error vector is: $\mathbf{e}_k = (N^{-1}P)^k \mathbf{e}_0$

 $\lim_{k\to\infty} M^k = 0$ is equivalent to

- ρ(M) < 1 as seen above
- There is a norm for which ||M|| < 1because $||M^i|| \le ||M||^i \to 0$

Jacobi method

(ロ)、(型)、(E)、(E)、 E) の(の)

$$A = D - L - U = \begin{pmatrix} a_{11} & 0 & \dots & 0 \\ 0 & a_{22} & \dots & 0 \\ \vdots & & \ddots & \vdots \\ 0 & 0 & \dots & a_{nn} \end{pmatrix} - \begin{pmatrix} 0 & 0 & \dots & 0 \\ -a_{21} & 0 & \dots & 0 \\ \vdots & & \ddots & \vdots \\ -a_{n1} & -a_{n2} & \dots & 0 \end{pmatrix} - \begin{pmatrix} 0 & -a_{12} & \dots & -a_{1n} \\ 0 & 0 & \dots & -a_{2n} \\ \vdots & & \ddots & \vdots \\ 0 & 0 & \dots & 0 \end{pmatrix}$$
(24)

Assuming no zeroes on the diagonal, $N(\omega) = \frac{1}{\omega}D$

$$\implies P(\omega) = \frac{1-\omega}{\omega}D + L + U \quad \text{in} \quad A = N(\omega) - P(\omega)$$
(25)

$$G(\omega) = (1 - \omega) + \omega D^{-1}(L + U), \quad \mathbf{g}(\omega) = \omega D^{-1}\mathbf{b}$$
(26)

for $\omega=1$ we get the Jacobi method, for $\omega\neq 1$ we have Jacobi overrelaxation (JOR)

Iterate until convergence Condition for exit if it's non-convergent is also needed

Gauss-Seidel and Successive overrelaxation

Start again from A = D - L - U, choose $N(\omega) = \frac{1}{\omega}D - L$ $\implies G(\omega) = (D - \omega L)^{-1}[(1 - \omega)D + \omega U], \quad \mathbf{g}(\omega) = \omega(D - \omega L)^{-1}\mathbf{b}$ Iteration equation:(after multiplication with $(D - \omega L)$

$$(D - \omega L)\mathbf{x}_{i+1} = (1 - \omega)D\mathbf{x}_i + \omega U\mathbf{x}_i + \omega \mathbf{b}$$
(27)

equivalent to:

$$\mathbf{x}_{i+1} = (1-\omega)\mathbf{x}_i + \omega D^{-1}(L\mathbf{x}_{i+1} + U\mathbf{x}_i + \mathbf{b})$$
(28)

Can be solved using forward substitution. Inverse of $(D - \omega L)$ not needed

$$x_{j}^{(i+1)} = (1-\omega)x_{j}^{(i)} - \frac{\omega}{a_{ii}} \left(\sum_{k=1}^{j-1} a_{jk}x_{k}^{(i+1)} + \sum_{k=j+1}^{n} a_{jk}x_{k}^{(i)} - b_{j}\right)$$
(29)

 $\omega = 1$ is called Gauss seidel method. $\omega \neq 1$ is Successive over-relaxation ω is called relaxation parameter weighted average of previous vector and Gauss-Seidel iterate

Gauss Seidel vs Jacobi

Jacobi (JOR):

$$\mathbf{x}_{i+1} = (1-\omega)\mathbf{x}_i + \omega D^{-1}(L\mathbf{x}_i + U\mathbf{x}_i + \mathbf{b})$$
(30)

$$x_{j}^{(i+1)} = (1-\omega)x_{j}^{(i)} - \frac{\omega}{a_{ii}} \left[\sum_{k=1}^{j-1} a_{jk}x_{k}^{(i)} + \sum_{k=j+1}^{n} a_{jk}x_{k}^{(i)} - b_{j} \right]$$
(31)

Gauss-Seidel (SOR):

$$\mathbf{x}_{i+1} = (1-\omega)\mathbf{x}_i + \omega D^{-1}(L\mathbf{x}_{i+1} + U\mathbf{x}_i + \mathbf{b})$$
(32)

$$x_{j}^{(i+1)} = (1-\omega)x_{j}^{(i)} - \frac{\omega}{a_{ii}} \left[\sum_{k=1}^{j-1} a_{jk}x_{k}^{(i+1)} + \sum_{k=j+1}^{n} a_{jk}x_{k}^{(i)} - b_{j}\right]$$
(33)

Same, except already known elements of \mathbf{x}_{i+1} are used instead of \mathbf{x}_i .

(ロ)、

convergence properties

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

if A is symmetric and positive definite than SOR process can be shown to converge for $0<\omega<2$ Typically one chooses $\omega=1.5-2$ to speed up convergence. $\omega<1$ is sometimes useful if it otherwise does not converge.

Jacobi iteration can be shown to converge for a strictly diagonally dominant matrix, as well as JOR for $0<\omega\leq 1$ for symmetric and positive definit A, JOR can be shown to converge for

$$0 < \omega < \frac{2}{\mu_{max}},\tag{34}$$

where μ_{max} is the maximal eigenvalue of $D^{-1}A$ Typically one takes $\omega = 2/3$.

a matrix A is strictly diagonally dominan if for every i

$$|a_{ii}| > \sum_{j \neq i} |a_{ij}| \tag{35}$$

Practical considerations

What should be the convergence criterion? we need $\|\mathbf{x}_k - \mathbf{x}\| < \epsilon$ but we don't know \mathbf{x} .

 $\|\mathbf{x}_{k+1} - \mathbf{x}_k\| < \epsilon$ is necessary, but not sufficient. (look at the sum $\sum_i 1/i$)

We can look at the residual $\mathbf{r} = \mathbf{b} - A\mathbf{x}$. First try: $\|\mathbf{b} - A\mathbf{x}_k\| < \epsilon$ This might also be misleading as

$$\|\mathbf{x} - \mathbf{x}_k\| = \left\| A^{-1}(\mathbf{b} - A\mathbf{x}_k) \right\| \le \left\| A^{-1} \right\| \|\mathbf{b} - A\mathbf{x}_k\| \le \left\| A^{-1} \right\| \epsilon$$
(36)

So the error norm could be large if $||A^{-1}||$ is large

Safest choice for unknown A:

$$\frac{\|\mathbf{b} - A\mathbf{x}_k\|}{\|\mathbf{b} - A\mathbf{x}_0\|} < \epsilon \tag{37}$$

Practical considerations 2

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

The iteration eq.: $\mathbf{x}_{k+1} = N^{-1}P\mathbf{x}_k + N^{-1}\mathbf{b}$ can be written as:

$$\mathbf{x}_{k+1} = \mathbf{x}_k - N^{-1}N\mathbf{x}_k + N^{-1}P\mathbf{x}_k + N^{-1}\mathbf{b} = \mathbf{x}_k + N^{-1}(-(N-P)\mathbf{x}_k + \mathbf{b}) = = \mathbf{x}_k + N^{-1}(\mathbf{b} - A\mathbf{x}_k) = \mathbf{x}_k + N^{-1}\mathbf{r}_k$$
(38)

$$\mathbf{r}_{k+1} = \mathbf{b} - A(\mathbf{x}_k + N^{-1}\mathbf{r}_k) = \mathbf{r}_k - AN^{-1}\mathbf{r}_k$$
(39)

So the pseudocode could be:

- **1** Initialize: $\mathbf{x} = \mathbf{0}, \ \mathbf{r} = \mathbf{b}$
- **2** While $\|\mathbf{r}\| > \epsilon \|\mathbf{b}\|$
- **3** Solve $N\mathbf{y} = \mathbf{r}$ for \mathbf{y}
- 4 update solution: $\mathbf{x} = \mathbf{x} + \mathbf{y}$
- **5** update residual: $\mathbf{r} = \mathbf{r} A\mathbf{y}$

Costs per iteration:

- **1** Calculating the norm costs n operations
- **2** Computing y costs n operations for Jacobi, $n^2/2$ for Gauss-Seidel
- Computing $A\mathbf{v}$ costs n^2 operations for a dense matrix (for sparse matrix with O(n) nonzero elements this costs is only O(n))

One iteration takes therefore $O(n^2)$ operations in contrast with $O(n^3)$ of the direct methods.

 \implies do we need O(n) iterations or less? The answer depends on many things... (what is A, what is ω ?) Often one finds out by experimenting

We want to get to the conjugate gradient method, let's first discuss the Gradient method (a.k.a Steepest descent, Richardson's method) Take

$$N = \frac{1}{\alpha}, \quad P = \frac{1}{\alpha} - A \tag{40}$$

with $\alpha > 0$. This leads to

$$\mathbf{x}_{k+1} = \mathbf{x}_k + \alpha (\mathbf{b} - A\mathbf{x}_k) \tag{41}$$

This converges for $0 < \alpha < 2/\lambda_{max}(A)$ for a positive definite A and might not converge for a non positive definite A

Geometric interpretation of gradient method

Suppose A is symmetric (hermitic) and positive definit ($\forall x : x^T A x > 0$) define

$$f(\mathbf{x}) = \frac{1}{2}\mathbf{x}^{\mathsf{T}}A\mathbf{x} - \mathbf{x}^{\mathsf{T}}\mathbf{b}$$
(42)

Since A is positive definit, this has a minimum. There we have $\nabla f(\mathbf{x}) = 0$

$$\nabla f(\mathbf{x}) = A\mathbf{x} - \mathbf{b} = 0 \tag{43}$$

Minumum of $f(\mathbf{x})$ solves the eq. $A\mathbf{x} = \mathbf{b}$

The iteration

$$\mathbf{x}_{k+1} = \mathbf{x}_k + \alpha (\mathbf{b} - A\mathbf{x}_k) \tag{44}$$

(日) (日) (日) (日) (日) (日) (日) (日)

steps along the negative gradient of $f(\mathbf{x})$. If α is small enough ($0 < \alpha < 2/\rho(A)$) than $f(\mathbf{x})$ decreases \rightarrow we might get to the minimum if we take small steps it's going to take long to get to the minimum. Idea: choose α such that $f(\mathbf{x} + \alpha(\mathbf{b} - A\mathbf{x}))$ is minimized \rightarrow optimal stepsize

$$f(\mathbf{x} + \alpha \mathbf{r}) = \frac{1}{2} (\mathbf{x} + \alpha \mathbf{r})^{T} A(\mathbf{x} + \alpha \mathbf{r}) - b^{T} (\mathbf{x} + \alpha \mathbf{r})$$
(45)

We get minimum from $\partial_{\alpha} f(\mathbf{x} + \alpha \mathbf{r}) = 0$

$$\implies \alpha = \frac{r^T r}{r^T A r} \tag{46}$$

Gradient method

Green: Gradient method with optimal stepsize

Can still take many steps to converge

Teaser: Red corresponds to Conjugate Gradient, which converges in two steps (in 2d)
