**Background:** Groundwater resources (and more generally the subsurface) are subject to different methods of utilization, which include among others water abstraction for public, industrial, or agricultural purposes, extraction or storage of energy, and construction activities. Changing climate conditions as well as the transition to a low-carbon society may change the interrelation between the different types of usage and thus may create conflicts between them (different from those today). For instance, the transition to a low-carbon society potentially involves enhanced use of hydroelectric power and thus hydraulic structures affecting the stream-aquifer interaction; likewise geothermal energy use or storage depending on the type of technology potentially affects water quantity or quality; more frequent and/or more severe drought may increase the demand for both public water supply and irrigated agriculture. This leads to the following research questions: How will the demands on aquifers change in the transition to a low-carbon society and how can these demands be met using groundwater resources sustainably in a changing climate?

**Goal:** This thesis aims to assess how the demands on an aquifer system potentially change in the transition to a low-carbon future, and to identify criteria for the sustainable use of groundwater resources in a changing climate.

**Methods and disciplinary background:** For a selected aquifer system (e.g., in the region of Graz), a groundwater model is developed that accounts for the impacts of various human activities such as water abstraction and hydraulic engineering or other construction activities under current conditions. Different pathways of the future development in the transition to a low-carbon society are explored and implemented in model scenarios to assess how groundwater resources are potentially affected by changing demands (e.g., increased water abstraction for public water supply or irrigation) or related construction activities (e.g., hydraulic structures for hydroelectric power) as well as by changing climate conditions. The results will be used to examine the applicability of the concept of groundwater sustainability (e.g., Alley et al., 1999; Gleeson et al., 2012) under changing environmental conditions.
