- Simulation of detector measurement

- Incoming photon flux

- Attenuated photon flux

- Energy resolution effects

- Background counts

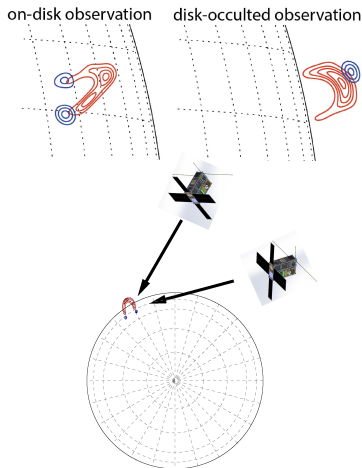

- Pseudo-experiment

- Quick comparison

- Summary

Stereo observations of solar flares

- ▶ **Energy spectrum** of **footpoint** and **coronal** sources
 - ▶ By looking at flares with **occulted footpoints** for one instrument
 - ▶ This overcomes an intrinsic limitation of indirect imaging
- ▶ **Directivity** of the **same source** as a function of the **energy**
 - ▶ This can be related to the **electron anisotropy**
- ▶ **STIX** and **MiSolFA** at next solar maximum
 - ▶ Good **cross-calibration** of the energy measurement is mandatory

Simultaneous measurement of coronal and footpoint sources

STIX

- ▶ **Spectrometer Telescope for Imaging X-rays** (STIX) is on the ESA/NASA **Solar Orbiter** mission
 - ▶ Orbiting **close to the Sun** (~ 0.3 au) with high inclination ($\sim 25^\circ$) during the next solar maximum
 - ▶ To be launched in Oct 2018
- ▶ **Indirect imaging** based on the moiré effect: 30 pairs of tungsten grids
 - ▶ 10 directions (20° steps)
 - ▶ 10 angular scales (7–180 arcsec)
- ▶ Photon detectors: **Caliste-SO** units developed by CEA Saclay
 - ▶ Better than 1 keV FWHM at 60 keV

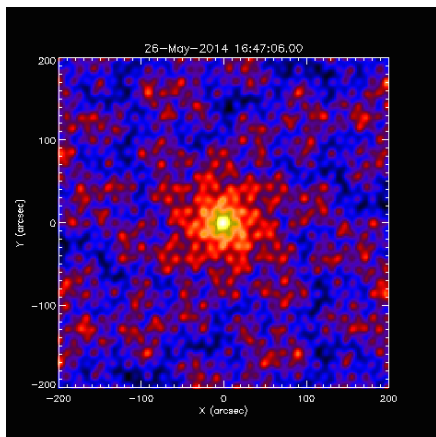

MiSolFA

- ▶ **Micro Solar-Flare Apparatus (MiSolFA)** will complement **STIX** observations
 - ▶ Smallest moiré imager (financed by SNF)
 - ▶ Angular range: 10–60 arcsec
- ▶ **6U** nanosatellite to be launched by the **Italian Space Agency**
 - ▶ Near-Earth polar orbit
 - ▶ 2–3 years overlap with STIX at solar max
 - ▶ Platform developed by **IMT Rome**
- ▶ **Imaging spectroscopy** with the **same photon detectors used by STIX**
 - ▶ Energy range: 10–150 keV
 - ▶ Special attention paid to energy cross-calibration

Quick comparison: imaging

Backprojection reconstruction of a point-source for
MiSolFA (left) and STIX (right)

Quick comparison: spectroscopy

Same toy source viewed by **STIX** (S) and **MiSoIFA** (M) with

- ▶ different attenuation
- ▶ different resolution
- ▶ different background
- ▶ same energy binning

Expected non-thermal counts

<i>E</i> bin (keV)	MiSoIFA counts/min				Relative uncertainty			
	M1	M3	M5	X1	M1	M3	M5	X1
28–31	64				0.13			
31–34	43				0.15			
34–38	38	242			0.16	0.06		
38–42	25	159	402	1021	0.20	0.08	0.05	0.03
42–46	17	108	274	696	0.24	0.10	0.06	0.04
46–50	12	76	192	488	0.29	0.11	0.07	0.05
50–55	11	68	171	435	0.31	0.12	0.08	0.05
55–60	7	46	118	298	0.37	0.15	0.09	0.06
60–70	9	57	145	368	0.33	0.13	0.08	0.05
70–80	5	32	82	208	0.44	0.18	0.11	0.07
80–90	3	20	50	128	0.56	0.22	0.14	0.09
90–100	2	12	31	79	0.72	0.28	0.18	0.11
100–115	2	11	29	73	0.74	0.30	0.19	0.12
115–130	1	7	18	45	0.95	0.38	0.24	0.15
sums:	240	840	1512	3840				
STIX	6k	21k	38k	96k				

Observation time with two instruments

- ▶ All flares **M1 or above** can be well measured by **MiSoIFA**
 - ▶ About 200 per year at solar maximum
- ▶ **Overlapping time** of **STIX** and **MiSoIFA**
 - ▶ STIX in science mode for 20% of time
 - ▶ MiSoIFA life time $\sim 50\%$
 - ▶ The same flare is viewed by both 50% of the time in which a flare is visible from Earth
 - ▶ **18 days per year**, hence ~ 10 (flares \geq M1)/year

Flares distribution

RHESSI flares map

Entries 103669

From HESSI Flare List generated on 2015-08-17 01:08

http://hesperia.gsfc.nasa.gov/hessidata/dbase/hessi_flare_list.txt

(Sometimes there is a problem with the roll angle)

Flares distribution

No correction applied for the distance to Sun (\rightarrow smearing)

RHESSI flares

Uniform longitude distribution

RHESSI flares

Latitude peaks at about $\pm 13.5^\circ$
with 6.3° std.dev.

Viewing angles

- ▶ Flare directions from RHESSI
- ▶ STIX taken uniform in longitude $\pm\pi$ rad and latitude ± 0.5 rad
- ▶ MiSolFA taken at the Earth (lon = 0, lat = 0)

Viewing angles

Limb flares

- ▶ 10–11% of all flares observed by each instrument fall beyond the limb by no more than 10°
 - ▶ About 20 (M1 or above) per year for each instrument
- ▶ The **coronal emission** will be measured for the flares with occulted footpoints for (only) one of the two instruments **half of the time**
- ▶ Accounting for the limited overlapping time, one expects to get a **few good simultaneous observations** of coronal and footpoint sources

Directivity measurement

- ▶ Which degree of **beaming** for the accelerated electrons?
 - ▶ Intuitively one expects quite significant anisotropy
 - ▶ but so far no convincing direct proof
- ▶ **STIX** and **MiSoIFA** will see the same source from different positions
 - ▶ Can compare **X-ray intensity at different energies**
 - ▶ Better constraints on **electron anisotropy**

Electron distribution

- ▶ N. Jeffrey & E. Kontar, *A&A* 536 (2011) A93
 - ▶ Electron distributions with different degrees of anisotropy
 - ▶ Photon emission and reflection (albedo)
 - ▶ Different flare locations, i.e. viewing angles
- ▶ Got total (direct + albedo) photon flux toward observer by Natasha (thanks!)
 - ▶ Photon spectrum in 10 bins uniform in $\mu \equiv \cos \theta$, where θ = heliocentric angle (viewed from Earth)
= viewing angle with respect to the local flare vertical direction
 - ▶ Parent electrons are isotropic, almost isotropic ($\Delta\nu = 4.0$), or beamed ($\Delta\nu = 0.5$)
 - ▶ Parent electrons have spectral index $\delta = 2$ and larger beaming for smaller $\Delta\nu$ (\approx std.dev. of pitch angle distribution)

Photon distributions from Natasha Jeffrey

- ▶ $\mu = 1 \rightarrow$ head-on source
- ▶ $\mu = 0 \rightarrow$ source viewed from side

Ratio of photon flux: smally anisotropy/isotropic

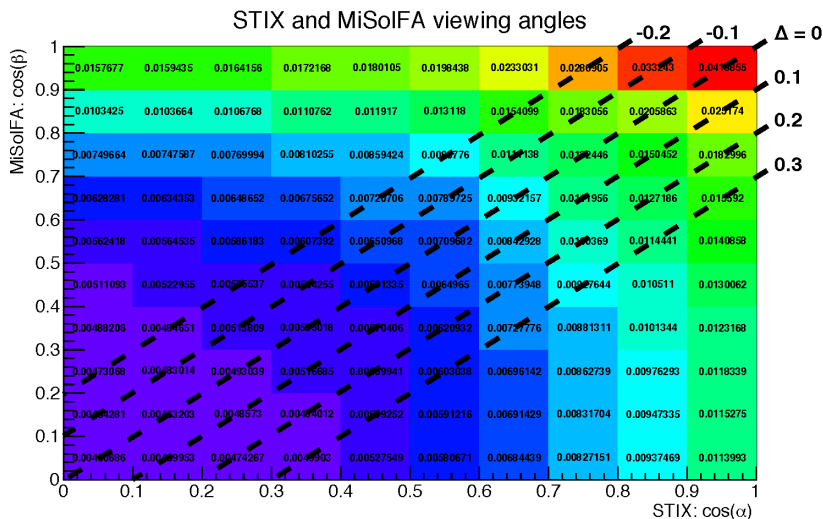

Sizable spectral difference vs. energy and viewing angle

Viewing angles

STIX and MiSoIFa viewing angles

Viewing angles

Viewing angles

Viewing angles

STIX - MiSoIFA

Use case: $\cos(\alpha) = 0.7-0.8$

$\cos(\beta) = 0.9-1.0$

STIX and MiSolFA viewing angles

Simulation of detector measurement

Goal: estimate **directivity vs. energy** with $\cos(\alpha) = 0.7\text{--}0.8$ (**STIX**) and $\cos(\beta) = 0.9\text{--}1.0$ (**MiSoIFA**)

1. Take photon flux by Jeffrey & Kontar DONE
2. Account for different attenuation DONE
3. Account for different energy resolution DONE
4. Account for different background DONE
5. Account for different (effective) collecting areas DONE
6. Simulate experiment (Poisson in each bin) DONE
7. Infer back about “true” input TO BE DONE

Incoming photon flux (scaled by $1e-3$)

Input on STIX, $\mu = 0.7-0.8$ Input on MiSolFA, $\mu = 0.9-1$ 

Flux attenuated by passive materials

Attenuated spectrum of S

Attenuated spectrum of M

Transmission

Energy resolution \rightarrow bin-to-bin migration

Add background counts

Expected spectrum of S

Expected spectrum of M

Background

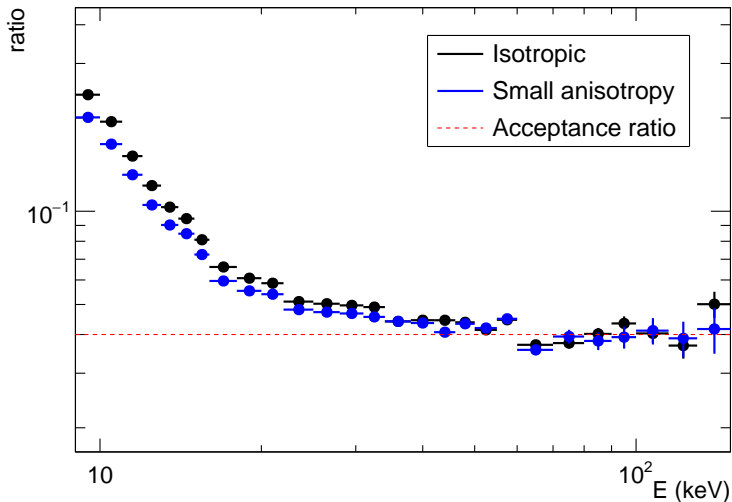

Pseudo-experiment: counts in 1 minute

Quick (and dirty) comparison

MiSolFA / STIX

Summary

- ▶ **STIX** and **MiSolFA** will provide stereo measurements
 - ▶ **Simultaneous** observation of **footpoint** and **coronal** sources
 - ▶ **Directivity** of the **same source** as a function of the **energy**
- ▶ Assuming an overlapping time of 5% (**18 days/year**) there will be **several good flares** per year
- ▶ **Angular separation** of 20° – 30° , or more
 - ▶ Can observe **energy-dependent directivity**
 - ▶ Better constraints on **electron anisotropy**
